Section A : Anatomy And Physiology

Name ..............................................

Form..............................................

Staff..............................................
Anatomy and Physiology

This section focuses on the impact of physical activity on the systems of the body and on young people’s participation and performance in physical activity as part of a balanced, active and healthy lifestyle.

Candidates will develop their knowledge and understanding of anatomical and physiological factors affecting body and mind readiness. This will lead to an improvement in the effectiveness and efficiency of their performance in roles such as performer, leader/coach and official.

The application of the knowledge gained will enable candidates to evaluate lifestyle choices critically in relation to their impact on body systems and lifelong participation in physical activity.

The skeletal and muscular systems

A general overview of the skeletal system is required and should include reference to the functions of the skeleton, the axial and appendicular skeleton and types of bone and cartilage.

Name the functions of the skeletal system

- ..................................................................................
- ..................................................................................
- ..................................................................................
- ..................................................................................

Functions

Label the structure of the long bone below
Long bone is one of five types of bone found in the skeleton. Identify and give examples of the other four types of bone.

Articular cartilage is one of the three types of cartilage found in the human body. Identify, outline the function and give examples of the other two types of cartilage.

Label the skeleton below and fill in the key to indicate the Axial and Appendicular skeleton.
Using the table and pictures below name the 3 classes of joint found in the body and state the differences between them.

<table>
<thead>
<tr>
<th>Class of joint</th>
<th>Mobility</th>
<th>Stability</th>
<th>Examples from the skeleton</th>
<th>Diagram</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fibrous</td>
<td></td>
<td></td>
<td></td>
<td><img src="image1" alt="Fibrous Joint Diagram" /></td>
</tr>
<tr>
<td>Cartilaginous</td>
<td></td>
<td></td>
<td></td>
<td><img src="image2" alt="Cartilaginous Joint Diagram" /></td>
</tr>
<tr>
<td>Synovial</td>
<td></td>
<td></td>
<td></td>
<td><img src="image3" alt="Synovial Joint Diagram" /></td>
</tr>
</tbody>
</table>

Fill in the table below showing the four main distinguishing features of a synovial Joint:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Structure</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ligament</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Synovial fluid</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Articular cartilage</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Joint Capsule</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Label three of the most commonly identifiable synovial joints

Synovial joints require a fine balance between stability and mobility. From your knowledge of the general structure of synovial joints:

1. List two features that increase joint stability, giving a specific function for each.

2. List two features that increase joint mobility, giving a specific function for each.

---

**KEY TERMS**

**Bursa (pl. bursae)**
A flattened fibrous sac lined with synovial fluid that contains a thin film of synovial fluid. Its function is to prevent friction at sites in the body where ligaments, muscles, tendons or bones might rub together.

**Meniscus (pl menisci)**
A wedge of white fibrocartilage that improves the fit between adjacent bone ends, making the joint more stable and reducing wear and tear on joint surfaces.

**Pad of fat**
A fatty pad that provides cushioning between the fibrous capsule and a bone or muscle.
The table below shows the mobility at the 5 different types of synovial joint. Fill in the two blank columns.

<table>
<thead>
<tr>
<th>Type of Synovial Joint</th>
<th>Examples from the skeleton</th>
<th>Description</th>
<th>Mobility</th>
</tr>
</thead>
</table>
| Ball and socket       | Acetabulum of pelvis
                      | A ball shaped head of one bone articulates with a cup like socket of an adjacent bone. | Movement can occur in three planes. This joint allows the greatest range of movement. |
| Cylindrical socket    | Humerus, Ulna             | A cylindrical protrusion of one bone articulates with a trough-shaped depression of an adjacent bone. | Movement is restricted to one plane. This joint allows bending and straightening only. |
| Condyloid             | Radius, Ulna              | A rounded or pointed structure of one bone articulates with a ring-shaped structure of an adjacent bone. | Movement is restricted to one plane. This joint allows rotation about its longitudinal axis only. |
| Ellipsoid              | Radius, Ulna, Carpals     | Similar to a ball and socket joint but with much flatter articulating surfaces forming a much shallower joint. | Movement can occur in two planes. This joint allows the second greatest range of movement. |
| Plane                  | Body of vertebra, cartilaginous disc | Articulating surfaces are almost flat and of a similar size. | Gliding allows movement in three planes, but it is severely limited. |
Joints, Muscles and Movements

Candidates should be able to demonstrate knowledge and understanding of the

- wrist: flexion and extension; wrist flexors and extensors;
- radio-ulnar: pronation and supination; pronator teres and supinator muscle;
- elbow: flexion and extension; biceps brachii and triceps brachii;
- shoulder: abduction, adduction, flexion, extension, rotation, horizontal flexion, horizontal extension, circumduction; deltoid, latissimus dorsi, pectoralis major, subscapularis, infraspinatus, teres major and teres minor; trapezius; the role of the rotator cuff muscles, supraspinatus infraspinatus, teres minor and subscapularis;
- spine (cartilaginous, gliding and pivot): flexion, extension, lateral flexion; rectus abdominus, external and internal oblique and the erector spinal group; sacrospinalis (the role of the transverse abdominus and multifidus in relation to core stability);
- hip: abduction, adduction, flexion, extension, rotation illiopsoas, gluteus maximus, medius and minimus, adductor longus, brevis and magnus;
- knee: flexion and extension; biceps femoris, semi-membranosus, semi-tendinosus, rectus femoris, vastus lateralis, vastus intermedius and vastus medialis;
- ankle: dorsi flexion, plantar flexion; tibialis anterior, soleus and gastrocnemius.

For each of the following movement identify a sporting example. Some of them have been done for you

- **Flexion at the Wrist** – *During the follow-through a set shot in basketball*
- **Extension at the Wrist**
- **Flexion at the Elbow**
- **Extension at the Elbow**
- **Flexion at the Shoulder**
- **Extension at the Shoulder**
- **Flexion at the Spine**
- **Extension at the Spine**
- **Flexion at the Hip**
- **Extension at the Hip**
- **Flexion at the Knee**
- **Extension at the Knee**
- **Horizontal flexion at the Shoulder** – *The throwing arm during the execution phase of a disc throw*
- **Horizontal extension at the Shoulder**
- **Abduction of the Shoulder**
- **Adduction of the Shoulder**
- **Abduction of the Hip** – *The upward phase of a straddle jump*
- **Adduction of the Hip**
- **Rotation of the Shoulder**
- **Rotation of the Hip**
- **Circumduction of the Shoulder**
- **Pronation of the Forearm**
- Supernation of the Forearm
- Lateral flexion of the Spine
- Dorsiflexion of the Ankle
- Plantar flexion of the Ankle

There are over 600 skeletal muscle in the body but, don’t worry, you do not need to know them all! Most of the muscles you will need to know are shown in the diagram below.

Most of the Muscles we will look at extend from one bone to another, are attached in at least two places and cross at least one joint.

Label the skeletal muscles in the diagram below

What is a muscle origin

What is a muscle insertion
Location and Actions of Specific Muscles

Fill in the tables below to show the locations and actions of the specific muscles involved in the joint movements.

<table>
<thead>
<tr>
<th>Joint</th>
<th>Joint movement</th>
<th>Muscle responsible</th>
<th>Location</th>

</table>

• contraction in the biceps brachii during upward phase of exercise.  
• the biceps brachii produces tension and shortens.  
• it pulls the forearm upwards to cause flexion of the elbow.

• contraction occurs in the biceps brachii during the downward phase of the exercise.  
• the biceps brachii produces tension and lengthens.  
• it slows the lowering of the forearm and controls extension of the elbow.

• contraction occurs in the biceps brachii when the muscle is holding the weight still.  
• the biceps brachii develops tension and stays the same length.  
• it stops flexion and extension of the elbow.

What is the difference between an Agonist, Antagonist and a fixator muscle?

Movement analysis of physical activity

Candidates should be able to:

• Carry out movement analysis making reference to joint type, the type of movement produced, the agonist and antagonist muscle (or muscles) in action and the type of muscle contraction taking place.

Look at the picture of the British gymnast.

Try to complete the grid with the joint type, joint movement, agonist, contraction type and antagonist.

Remember that when the grid asks for the right or left side, it means the performers right or left side.

Fill in the table above using the photo of tiger Woods.
Muscle fibre types in relation to choice of physical activity

Candidates should be able to:

- describe the structure and function of the different muscle fibre types (slow oxidative, fast oxidative glycolytic and fast glycolytic) in relation to different types of physical activity;
- explain how an individual's mix of muscle fibre type might influence their reasons for choosing to take part in a particular type of physical activity.

Key terms

Fill in the information for the titles of the key terms below. Try to include as much information as possible.

Aerobic Exercise

</table>
Impact of different types of physical activity on the skeletal and muscular systems

Candidates should be able to:

- evaluate critically the impact of different types of physical activity (contact sports, high impact sports and activities involving repetitive actions) on the skeletal and muscular systems (osteoporosis, osteoarthritis, growth plate, joint stability, posture and alignment) with reference to lifelong involvement in an active lifestyle.

Use the pictures below to describe what osteoporosis is and how it affects your bones density.
How does physical activity affect Osteoporosis?

What is a Growth Plate?

What can happen to the Growth plate during physical activity? Give examples of types of sports, actions and the people that growth plate injuries may affect.
It appears that there may be a slight disagreement to the value of high impact activities to young people. On one hand health professionals promote this type of activity to increase bone density, but on the other hand, the risk of damage to the growth plate is high.

Could you suggest some guidelines for a young performer taking part in high impact sports.

Use the pictures below to describe what Osteoarthritis is and how it affects movement.
How does physical activity affect osteoarthritis?

Weightlifter are prone to early development of osteoarthritis of the knee due to their high body weight. Early development of osteoarthritis in the knees of some football players has been attributed to repeated trauma to ligament, bones and cartilage. Interestingly, however, recent studies have not found an increased risk of osteoarthritis in long-distance runners. Can you suggest reasons for this?

There are three main factors that affect joint stability. Names and describe all three in relation to the knee joint.

Motion and Movement

Basic concepts of Biomechanics

Candidates should be able to:

- define Newton’s Laws of Motion;
- describe the types of motion produced (linear, angular or general);
- describe the effect of size of force, direction of the force and the position of application of the force on a body;
- define centre of mass;
- explain the effect of changes in the position of the centre of mass and the area of support when applied to practical techniques;
- carry out a practical analysis of typical physical actions.

State Newton’s laws and give a practical example for each

Newton’s first law of motion – Law of ‘INERTIA’

Example..........................

Newton’s second law of motion – Law of ‘ACCELERATION’

Example..........................

Newton’s third law of motion – Law of ‘REACTION’

Example..........................

What is meant by the term ‘body’?

</tbody>
</table>
The cardiovascular and respiratory systems in relation to the performance of physical activity and sustained involvement in an active and healthy lifestyle.

Content assumes prior knowledge of the structure and function of the cardiovascular and respiratory systems.

Response of the cardiovascular system to physical activity

Candidates should be able to:

- describe the link between the cardiac cycle (diastole and systole) and the conduction system of the heart;
- describe the relationship between stroke volume, heart rate and cardiac output and resting values for each;
- explain the changes that take place to stroke volume, heart rate and cardiac output during different intensities of physical activity;
- describe the distribution of cardiac output at rest and during exercise (the vascular shunt mechanism);
- explain the role of the vasomotor centre and the involvement of arterioles and pre-capillary sphincters;
- explain how carbon dioxide and oxygen are carried within the vascular system; how effective transportation of carbon dioxide and oxygen within the vascular system aids participation in physical activity; how smoking affects transportation of oxygen;
- define blood pressure and identify resting values;
- explain the changes that occur during physical activity and hypertension;
- explain how venous return is maintained; the effects that a warm-up and cool-down period has on the cardiovascular system; how venous return affects the quality of performance;
- evaluate critically the impact of the different types of physical activity on the cardiovascular system (coronary heart disease (CHD); arteriosclerosis, atherosclerosis, angina, heart attack) with reference to lifelong involvement in an active lifestyle.

On the diagram opposite place the following things

1. Directional arrows to show blood flow around the body
2. Oxygenated and deoxygenated blood

Why is the heart a double pump?

What is the main function of the heart?

Imagine you are a red blood cell travelling through the body. Describe, step by step, the route taken and whether you are oxygenated or deoxygenated at each stage starting from the right atrium.
Draw and add the following labels to the diagram

1. SA node
2. Right and Left atria
3. AV node
4. Bundle of His
5. Bundle branches
6. Purkinje Fibres

Use the numbered labels to describe the action of the conduction system in controlling a heartbeat

Annotate the flow diagram to include the stages of the conduction system of the heart.

**DIASTOLE (0.5 secs)**
1. Both atria fill with blood. AV valves closed.
2. Atrial blood pressure rises above ventricular pressure.
3. Rising blood pressure forces AV valves open and blood **passively** passes into both ventricles. Semilunar valves closed.

**SYSTOLE (0.3 secs)**
4. Both atria contract, **actively** forcing the remaining atrial blood into ventricles.
5. Semilunar valves remain closed.
6. Both ventricles contract, increasing ventricular pressure.
7. Aortic and pulmonary valves forced open. AV valves closed.

**VENTRICULAR SYSTOLE**
8. Blood forced out into: aorta to body tissues/muscles = **Stroke volume**; pulmonary arteries to lungs. N.B. Only 40-50% blood is ejected at rest during ventricular systole (SV).

9. Diastole of the next cardiac cycle begins. Semilunar valves close presenting backflow of blood from aorta and pulmonary arteries.
Define heart rate (HR)

What is the equation for working out maximum heart rate?

\[ \text{MAX HEART RATE (HR)} = \text{AGE} - \text{AGE} \]

What is an average resting heart rate?

Define stroke volume (SV)

What is an average resting stroke volume?

Define Cardiac output (Q) in terms of heart rate and stroke volume

\[ \text{Q} = \text{HR} \times \text{SV} \]

If an athlete has a resting Q of 5L/min and a resting heart rate of 60, what is their resting SV?

<table>
<thead>
<tr>
<th>Definition</th>
<th>Heart rate</th>
<th>Stroke Volume</th>
<th>Cardiac Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Untrained</td>
<td>70bpm</td>
<td>70/72ml</td>
<td>5000ml (5L)</td>
</tr>
<tr>
<td>Trained</td>
<td>50bpm</td>
<td>100ml</td>
<td>5000ml (5L)</td>
</tr>
</tbody>
</table>

Look at the table above and give possible reasons as to how and why HR and SV at rest increases in a trained athlete compared to an untrained athlete.

What is sub maximal exercise?

As an athlete begins to exercise the heart must increase its output. Why does the heart need to do this?
Look at the graph above and comment on the relationship between stroke volume and sub-maximal exercise (60%)

To understand why stroke volume increase, we need to identify the factors that determine it. Put simple, stroke volume is determined by the heart’s ability to fill and empty at each beat.

1. The heart’s ability to fill is dependent on:
   - ..........................................................................................................................
   - ..........................................................................................................................
   - ..........................................................................................................................

2. The heart’s capacity to empty is dependent upon:
   - ..........................................................................................................................
   - ..........................................................................................................................

As the runner continues towards their maximal exercise intensity level, they will need to increase their cardiac output (Q) further. However, their stroke volume has already reached its plateau (maximal value) during sub-maximal work, what else can happen to increase the Q further?
Heart Rate Response To Submaximal and Maximal Exercise

Look at the graph above and analyse the difference and similarities between the heart rates of maximal and sub maximal exercise

Anticipatory rise

Sharp rise at onset of exercise

Plateau during exercise

Recovery
Why does cardiac output increase during exercise?

</tr>
</tbody>
</table>

To help with the %’s use the formula \( \frac{\text{Tissue ml}}{\text{Total ml}} \times 100 = \% \text{ of Distributed blood} \)

Once you have completed the table fill and label to two pie charts below for the distribution of blood at rest and maximal exercise

Why does an athlete move blood to the skin during exercise?

Can you explain why there is a drop in distributed blood to the skin when an athlete is working at maximal intensities
Let us use the example of the cyclist to explain the distribution of blood and why they fainted after a bout of exercise.

At rest and prior to training, the cyclist’s cardiac output (Q) was spread around the _______ organs and _________ related to resting needs for ______________. When exercise began, __________ muscle in the legs increase its demand for ______________ and blood flow was increased. In contrast, the tissue and organs not directly required during exercise (l__________, k__________, intestines etc.) had their blood flow ________________.

Initially blood flow to the skin surface _____________ to help decrease rising ______________, but as the intensity of exercise increased, the ever-increasing demand for ________________ by the muscles overrode the need to ___________ temperature, and blood flow to the skin _________________. Once exercising stopped, Q was gradually redistributed back towards resting levels as the body recovered.

Fainting

In immediately stopping and standing still, blood __________ occurred in the pocket valves of the veins in the cyclist’s legs due to insufficient p__________ to maintain venous return against g_____________. By immediately stopping the cyclist switched off the m__________ and r__________ pump mechanisms of ______________ __________. As venous return decreases, __________ _____________(SV), and therefore Q, decreased ______________ (Law of the heart) and reduced blood pressure thus threatening the blood supply to the brain which simply responded by making the cyclist dizzy and faint.

The cyclist fell which lowered the head, which aided __________ ______________ and therefore blood pressure, SV and Q, restoring blood flow to the brain. Recall that an active __________ __________ is essential to maintain venous return and prevent blood pooling.

Which control centre is responsible for the redistribution of blood during rest and exercise and where is it found in the body?

Which part of the nervous system is used to send messages to control the redistribution of blood?

Which of the blood vessels is primarily responsible for the vascular shunt mechanism?
The vasomotor control centre receives information from two main receptors. What are they, where are they found and what do they detect?

</table>

Do you meet the recommended minimum guidelines for any of the three columns? If no what were you missing?
What generic exercise recommendations would you give to reduce the risk of cardiovascular disease?

Response of the respiratory system to physical activity

Candidates should be able to:

- describe the mechanics of breathing at rest and the respiratory muscles involved (including the diaphragm and external intercostals muscles);
- explain the changes in the mechanics of breathing during physical activity including reference to additional muscles involved (sternocleidomastoid and pectoralis minor) and the active nature of expiration (internal intercostals and abdominal muscles);
- explain how changes in the mechanics of breathing during physical activity are regulated by the respiratory centre (both neural and chemical control) to take into account the demands of different intensities of physical activity;
- describe the process of gaseous exchange that takes place between the alveoli and the blood and between the blood and the tissue cells. (An awareness of partial pressure is required but candidates will not be expected to provide specific respiratory pressures.);
- explain the changes in gaseous exchange that take place between the alveoli and the blood and between the blood and the tissue cells (increased diffusion gradient and accelerated dissociation of oxy-haemoglobin) as a direct result of participation in physical activity;
- explain the effect of altitude on the respiratory system and how it influences the performance of different intensities and activity;
- evaluate critically the impact of different types of physical activity on the respiratory system with reference to lifelong involvement in an active lifestyle (to include an awareness of asthma and smoking).

What is the primary aim of the respiratory system?
The respiratory system performs three main processes which are linked via the heart and vascular systems. What do the three processes mean?

1. **Pulmonary ventilation**
   
   Label the diagram below with the structures of the respiratory system.

2. **External respiration**

3. **Internal respiration**
Put the structures from the diagram in order to show the path of atmospheric air to the site where gaseous exchange takes place.

Label the structure of an alveolus.
The alveoli are the sites at which gaseous exchange takes place. But how does an alveoli increase the efficiency of gaseous exchange?

Label the diagram of the lungs below

Why is there a double membrane filled with pleural fluid surrounding the lungs?
What is meant by the terms inspiration and expiration?

The mechanics of breathing are easier to learn by linking five steps

1. Muscles -
   ............................................................................................................................
2. Movement -
   ............................................................................................................................
3. Thoracic cavity volume -
   ............................................................................................................................
4. Lung air pressure -
   ............................................................................................................................
5. Inspiration or expiration -
   ............................................................................................................................

When respiration takes place at rest there is an active inspiration and passive expiration. Briefly describe what is meant by active and passive?

Label the muscles and their contractile state during active inspiration and active expiration at rest.

As we begin to exercise the demand for oxygen increases. We therefore begin to use additional muscles (as shown above) to affect our breathing in two ways. What are they?

1. ........................................................................................................................................
2. ........................................................................................................................................

In pairs, one partner completes three minutes of aerobic exercise (light run?) and the other partner completes three minutes of anaerobic work (shuttle runs at speed?) Record the following breathing frequencies (one minute values) – Breathing at rest, one minute after completion, and how long it takes to return to normal.

<table>
<thead>
<tr>
<th>Name</th>
<th>Rest</th>

What are the definitions of the following lung volumes?

**Tidal Volume (TV)**

**Frequency (f)**

**Minute ventilation (VE)**

Use the following normal values to calculate the minute ventilation of a normal performer

\[
\text{TV} = 500\, \text{ml} \quad \text{Frequency} = 15 \, \text{breaths}
\]

What equation did you use to calculate the minute ventilation of an athlete?

A Tidal volume (TV) of 500ml and a frequency (f) of 12 produces a Minute Ventilation (VE) of 6L/min. Explain why increasing the frequency to 24 and a Tidal Volume of 4000ml per breath during exercise would be beneficial to an aerobic athlete.

On the graph can you work out the tidal volume value of the performer at rest?

What is the tidal volume of the performer during exercise?

Why does the graph not go down to 0?
The exchange of oxygen and carbon dioxide takes place in the lungs and tissue and are called external and internal respiration respectively.

What is the process of Diffusion and how does the diffusion gradient affect the movement of oxygen and carbon dioxide?

What does the term Partial Pressure refer to when describing the movement of gases within the body?

Label the diagram with a high and low partial pressure for oxygen and carbon dioxide.
What is gaseous exchange? And where does it take place?

What does an Oxygen-Haemoglobin Dissociation curve show us?
……………………………………………………………………………………………………………………………………………………………
……………………………………………………………………………………………………………………………………………………………
……………………………………………………………………………………………………………………………………………………………
……………………………………………………………………………………………………………………………………………………………

What does the word saturation mean?
……………………………………………………………………………………………………………………………………………………………
……………………………………………………………………………………………………………………………………………………………
Can you label the Oxygen-Haemoglobin Dissociation curve for a performer at rest.

At rest, the PP of oxygen in the lungs is 100mmHg. Follow this line up from the 100mmHg and see where it intersects the curve. Draw a line across to the ‘y’ axis and record the value.

If you have followed the steps correctly you should have a figure of around 98%. This represents the percentage of saturation/association of oxygen with haemoglobin in the alveoli capillary blood.

At rest the PP of oxygen in the tissue/muscle is around 40mmHg. Repeat the steps above to calculate the percentage saturation/association of oxygen and haemoglobin in the tissue/muscles’ capillary blood.

What has happened to the 25% of the oxygen that was associated with haemoglobin?

[Graph showing the Oxygen-Haemoglobin Dissociation curve]
Where does the association and dissociation of oxygen take place in order to maintain an efficient supply of oxygen to the working muscles during exercise?

Association

Dissociation

The red curve on the left of the diagram represents the normal curve we have already looked at. Read off the values for the percentage saturation/association of oxygen and haemoglobin in the tissue/muscles using the blue curve on the right.

What effect does moving the curve to the right have on the saturation of haemoglobin if we assume the PP of oxygen remains the same in the tissue?

What are the benefits for an athlete of the curve shifting to the right?
Place an arrow to show the direction of diffusion during external respiration

<table>
<thead>
<tr>
<th>Partial pressure</th>
<th>Alveolar air</th>
<th>Direction of diffusion (High to low PP)</th>
<th>Alveoli capillary blood</th>
<th>Diffusion gradient</th>

RCC Overview

1 Medulla Oblongata

5 Inspiratory Centre

9 Expiratory Centre

4 Temperature receptors
- Increase in blood temperature

3 Proprioreceptors
Located in active muscles and joints.
- Increase in motor movements

2 Chemoreceptors
Located in medulla and carotid arteries.
Primary factor
- Increase in pCO₂
- Increase in pH
- Decrease in pO₂

8 Lung stretch receptors
- Increased stretch during inspiration

6 Inspiratory muscles
External intercostals and diaphragm
7 Additional muscles during exercise
- Increase depth of breathing

10 Expiratory muscles
Internal intercostals, abdominals and obliques
- Increase rate of breathing

Overview of respiratory regulation

At rest
The medulla oblongata (1) contains inspiratory and expiratory centres. When chemoreceptors (2), active muscles (3) and increasing temperature (4) stimulate the inspiratory centre (5), this stimulates the inspiratory muscles (6) to contract increasing the volume of the thoracic cavity and drawing air into the lungs. Inspiratory muscles passively relax decreasing volume thoracic cavity and air is expired.

Exercise
As (1) to (6) but during exercise the inspiratory centre stimulates additional respiratory muscles (7) which increases the depth of breathing. This stimulates stretch receptors (8) in the lungs, which stimulate the expiratory centre (9) to stimulate the expiratory muscles (10) to contract. This causes a forced expiration which reduces the duration of inspiration. This decreases the depth and therefore increases the rate of breathing.
What is the difference in air pressure at higher altitude?

What is EPO? And what does it do?

What is hypoxia?

Use the diagram below to describe the effects of attitude training.
There are three main methods of altitude training which have mixed and conflicting research. Research and discuss the three methods of altitude training below in relation to their benefits to improving performance.

1. Live High Train High – LHTH
2. Live Low Train High – LLTH
3. Live High Train Low – LHTL
The net effect on the respiratory system of training is an increase in its efficiency to supply O\(_2\) to the working muscles during higher intensities of physical activity. What are the specific respiratory adaptations that help improve this efficiency?

1. Respiratory structures

2. Breathing Mechanics

3. Respiratory Volumes

4. Diffusion

What is VO\(_2\) Max?
Asthma

What are the symptoms of Asthma?

How is Asthma measured?

What are the triggers of Asthma?

What are the medical treatments for Asthma?
What are the non-medical treatments for Asthma?

What is Inspiratory Muscle Training (IMT) and what possible effects could it have on Asthma?

Use the pictures below and your own knowledge to describe the health effects of Smoking?
What effects does smoking have on performance?
